INTRODUCTION AND BACKGROUND

As skiing diversifies into sub-types, it is important to understand each type of skier, and how they identify with their sport of choice. Backcountry skiing is growing at a rate of 500,000 new participants every 2 seasons, while lift-service skiing has leveled off in Vermont over the last 10 years. This understanding can diversify management of recreation areas.

Through Tajfel’s social identity theory and Stryker’s structural symbolic interactionism, utilizing surveys and focus groups during the 2017/2018 season, this pilot study explores:

- Intrinsic commitment: internal affective significance
- Extrinsic commitment: social ties
- Salience of skier identity: Prominence among other identities

We believe backcountry skiers will have higher levels of intrinsic commitment, extrinsic commitment (social ties), and salience of skier identity than lift-service skiers. Both groups will display similar monetary commitment to skiing. Information gathered from this pilot study will be used to focus research questions for the 2018/2019 season.

METHODS

- Participants were surveyed at three data collection sites, base lodge or trail head. Convenience sampling was used to create a sampling methodology for the full study.
- Survey included questions about demographics, frequency of skiing, type of skiing, monetary input into skiing, extrinsic commitment, and intrinsic commitment.
- A focus group was held to shape future questions on how lift-service and backcountry skiers view skiing.

STUDY DESIGN

A pilot study explores:

- Interactionism, utilizing surveys and focus groups during the 2017/2018 season, this pilot study
- Gathered from this pilot study will be used to focus research questions for the 2018/2019 season.
- Both groups will display similar monetary commitment to skiing. Information gathered from this pilot study will be used to focus research questions for the 2018/2019 season.

Survey: It was found that backcountry skiers responded with significantly higher levels of intrinsic commitment and significantly more social ties through skiing than lift-service skiers did (Figure 1).

Table 1. Mean scores of intrinsic measures of commitment. Measured agreeability on Likert scales from -2 to +2.

CONCLUSIONS AND FUTURE DIRECTIONS

Backcountry skiers had higher levels of intrinsic commitment and social ties to skiing, though did not have a relationship to level of experience with skiing.

- Backcountry skiers spent more on skiing than lift-service skiers did, though not a significantly different portion of their income.
- Higher levels of commitment could reveal a more salient skier identity in backcountry skiers.
- Catering towards these commitment factors when managing recreation areas could improve user experience.

The preliminary survey revealed measures of commitment, but failed to measure how high in a salience hierarchy the skier identity was for both lift-service and backcountry skiers. Commitment and salience will be measured during the winter 2018/2019 season.
